## PREFACE

This is the first in a series of Technical Notes on the utilization of the computer facilities at Letterman Army Institute of Research to assist in mutagenicity testing as part of the institute's toxicology program. These reports will detail the use of the computer in labelling articles, recording, storing, and retrieving data, and data analysis. Both the Salmonella/Mammalian microsome (Ames) and the Drosophila melanogaster sex-linked recessive lethal mutagenicity assays will be covered. These reports are not intended to cover in detail the rationale or the technique involved in mutagenicity testing by these assays.

#### ACKNOWLEDGMENTS

The authors express their appreciation to the Information Sciences Group for making the computer facilities readily available and to those who have made suggestions for improving the utility of the programs described herein.

**COMPUTER-ASSISTED LABELLING IN MUTAGENICITY TESTING:**  
The Ames Salmonella/Mammalian Microsome Mutagenicity Assay--Jederberg, Sauer, and Pulliam

The Ames Salmonella/Mammalian Microsome Mutagenicity Assay is one of a standard bank of tests used for the detection of mutagenic agents (1). It involves the use of several genetically altered strains of Salmonella typhimurium - each with a specific mutation in the histidine operon. The test is based on a reverse mutation to a wild-type, prototrophic phenotype induced by the test compound. In addition to the reversion, activation by microsomal enzymes is also used to determine if any potential promutagens exist.

This type of assay requires the labelling of agar plates with information concerning the dilution of the test substance, the particular bacterial mutant, the presence or absence of microsomal enzymes, and replicates. Since all assay components are added to a tube of top agar prior to plating, a corresponding number of labels must also be generated. This requires the production of approximately 400 labels per test substance and approximately 300 labels for controls per assay. These items are currently hand-labelled in most laboratories. We have designed and implemented a FORTRAN V program (with subroutines) for the rapid generation of the large number of unique labels. The use of this system has greatly reduced the time spent identifying material, guaranteed accurate correspondence between the top agar tube and the target plate, and insured continuity from the initiation to the termination of the assay.

This technical note describes the programs used for labelling the numerous articles used in performing the assay. For a complete discussion of the nature of the required materials for the assay, the reader is referred to reference 1.

**PROGRAM DESCRIPTION**

The main program (Appendix A) calls a series of subroutines to generate sterility, quality, positive and negative control, test compound, and dilutional control labels (Appendix B through K). The labels are generated in the sequence that they will be used in setting up the assay.

Sample runs appear in Figures 1 through 11 (Appendix L). As the program prepares the labels, it displays a message (Figure 1). Up to ten test compounds are allowed and each is designated with an

alphanumeric field of up to ten characters in length (AN/10). Up to ten dilutions of each test compound are allowed. (In the figure, the underlined characters are entered at the time of program execution by the user.)

The text for sterility control labels appears in Figures 2 through 5. Sterility controls include (a) minimal glucose agar (MGA) and the nutrient broth (Figure 2), without the presence of mammalian microsome solution (S-9), (b) the top agar and S-9 mix (Figure 3), (c) the diluent and histidine-biotin mixture (Figure 4), and each of the bacterial cultures (Figure 5).

A check is made on the characteristic nutrient requirements of the strains used (Figure 6).

Quality controls check the characteristic responses of the mutant strains to chemical and light stimuli (Figure 7).

The response of each strain to known positive mutagens is validated (Figure 8).

The test strains are grown, both, with no S-9 and with S-9 to check the spontaneous mutation rates (Figure 9).

At the beginning of each test compound, the diluent used for that compound is checked, both, with and without S-9 (Figure 10).

Each test compound is checked with each tester strain of microorganism in the presence and absence of S-9 at each dilution of the test compound (samples represented in Figure 11).

At the end of the run the negative and sterility controls are run again.

After the text for all the labels has been generated and stored in the file labelled "DLABELS" the user is so notified and may print the labels out on an appropriate device (usually a printer with tractor feed). The test is formatted so that the labels should be printed on continuous-feed single-width stock material. These may be obtained from most distributors of computer supplies and office forms. The labels are standard 1 x 3.5 inches.

#### DISCUSSION

By utilizing the program and subroutines presented in this report, we have realized a significant saving in time for the preparation of materials for the Salmonella/Mammalian microsome mutagenicity assay. The labels have also been of great help in maintaining order and

uniformity while running the assay. The labelling has been beneficial in maintaining conformity with the rigid requirements of the Food and Drug Administration's Good Laboratory Practices Act (2).

**CONCLUSION**

**None**

**RECOMMENDATION**

**None**
